

## Second Assessments

Scores for weed control and crop damage at the second assessment had been submitted for only three centres when this paper was prepared, and therefore no data is presented.

### DISCUSSION

The three herbicides are of low mammalian toxicity at the rates used and can be applied at medium volume through a farm sprayer. Agitation must, however, be efficient, and any herbicide remaining in the tank after treatment may solidify after settling.

Each reduced infestations of some of the more important weed species commonly found in the kale crop, but complete kills were rare. The outstanding success was in the control of Chenopodium album, the worst weed encountered over the country as a whole, which hitherto could only be killed with any degree of reliance by sulphuric acid. The latter is a costly operation usually carried out as a contract service which is becoming increasingly difficult to obtain. Limited evidence shows that Sinapis arvensis may be resistant, but although this species occurs much more widely in the kale crop than is indicated in these experiments, a satisfactory control of young plants can, under dry conditions, usually be obtained at relatively low cost with sodium monochloroacetate, which can be applied through a farm sprayer. The results for Polygonum persicaria will be of particular interest in northern and western districts. On present evidence, there is a good chance of killing seedlings, whilst more mature plants may at least be checked sufficiently to be kept below the level of the growing crops. This degree of control will probably be acceptable to most farmers as an alternative to sulphuric acid and sodium monochloroacetate - the only other effective treatments.

Plant counts at Pangbourne show that crop mortality can be severe in a stand of kale containing a high proportion of young plants. Observations at several centres provide supporting evidence that young plants are more easily killed than those which are more mature, and the data from all the trials indicates a possible trend towards greater initial damage in crops sprayed at the 2-3 leaf stage than in those treated later. It remains to be seen whether this will be reflected in the yield figures. Where damage of any kind occurs, the effects are most marked at the 6 oz/ac dose, but can be severe with ametryne and simetryne at 4 oz/ac. Damage was, however, appreciably less on average than that associated with normal application rates of sulphuric acid and sodium monochloroacetate, and in several trials good weed control was obtained with no more than a slight check to the stand. A nitrogenous top dressing applied after treatment would no doubt help recovery when damage is severe, and assist the additional control resulting from crop competition.

The use of 'G 34360' against the more susceptible weeds would tend to keep crop damage to a minimum. An application of 4 oz/ac appears to be adequate in most cases. The data at present available is insufficient to indicate whether ametryne and simetryne at 4 oz/ac would have sufficient additional advantages in the control of the more resistant species to make them competitive with 'G 34360' at 6 oz/ac.

The fact that seedlings of Polygonum persicaria are more easily killed than older plants has been mentioned, but no other relationship between the stage of growth of the more important weeds and the effectiveness of the treatments could be established from the scores, mainly because the range of size of the weeds was appreciable at many centres.

The effects of the type of growth of the crop when treated (slow or active), and of the weather after spraying have not been examined, because the evidence of the second assessments is needed for a complete statement.

These herbicides do not solve the recurrent problem of re-infestation after the spraying of slow growing crops, such as occurred with Chenopodium album at Holsworthy and Fumaria officinalis at Castle Combe. The encouragement of crop competition by good husbandry is still the only partial solution to this difficulty.

#### Acknowledgments

The assistance of the farmers who provided sites for the trials is gratefully acknowledged. Thanks are also due to Mr. J. G. Elliott and Dr. K. Holly of the Weed Research Organisation, for their help in the planning of the experiments, and to the following members of the N.A.A.S.: Messrs. D.W. Beesley, J.E. Brooke, E.R. Bullen, W.Q. Connold, G.A. Dowsé, S.A. Evans, G.L. Gladwell, D. Hardy, E. Harris, B. Helmsing, R.J. Hughes, F.W. Jameson, M.J.A. Jenkins, G.W. Jones, D.J. MacDougall, E.O. Moore, J.R. Neild, J.B. Page, J. Park, J. Proctor, R.J. Tate, G.A. Toulson and G.R. Wilson who have all been concerned with the work at various stages.

### Discussion of preceding three papers

Mr. G.E. Furse In regard to Mr. Powell's paper, our S.W. Region N.A.A.S. centres included weed control in a range of kales - Marrow Stem, Thousand Head; a mixture of Marrow Stem and Thousand Head; kale with a few swedes; and rape - all of which are important to us in our big acreage of agricultural Brassica crops in the S.W. Fathen has long been a major problem with us in these crops. Mr. Elliott suggested in one of his remarks that if fathen is rather forward in growth the results may be poor. We had some evidence on small plots at Bristol, which, for various reasons, were sprayed late when the fathen was almost in flower and the kale well advanced; we obtained excellent control of the fathen, with less damage to the kale than when sprayed earlier. This could be of great importance to us in the years immediately ahead as most of our advisory queries on this weed come to us when the fathen is forming a canopy over the kale of 1ft to 2ft high. At one of our centres (Holsworthy, Devon) although control of fathen seedlings present at the time of spraying was good, late-germinated seedlings, which occur very commonly in the S.W., came in a few weeks later and the final appearance of the plots suggested no control at all. Later spraying than was done in these plots may be the ultimate answer to fathen, which tends to germinate late in the season. I would like to put one question to Mr. Elliott or to Messrs. Fisons representatives about the likely toxicity of the herbicide. We have been told that there is no toxicity hazard to stock where early sprayed kale is later fed at the normal winter feeding time, but what are the risks if cattle and sheep "break into" crops soon after spraying has been done.

Dr. R.K. Pfeiffer As far as toxicity is concerned, I cannot make an official statement; but I am quite prepared to eat kale the day following spraying with these herbicides!

Mr. J.G. Elliott We need more experience of methods of dealing with second germinations of weeds which occur usually as a result of wet, warm weather following a dry spell. Where herbicides are to be used in kale, the weeds must be encouraged to germinate and grow with the crop, because this is the situation that a selective herbicide requires. To achieve this we will have to educate farmers away from their present tendency to work the land before planting which may lead to irregular emergence of crop and weeds due to moisture loss in the seedbed. We are working out costs of production on the basis of the new concept of using herbicides in kale growing. When compared with maize, it may be that kale will be the cheaper form of starch equivalent.

Mr. H.A. Roberts I should like to draw attention to another important potential use of "G34360" in the horticultural Brassicas, which represent a large acreage. There is an increasing tendency to direct-drill these crops rather than transplant, and success with this method presupposes effective weed control. Our preliminary experiments at Wellesbourne with such crops as cabbage and Brussels sprouts confirm the results described for kale, both as regards crop tolerance and weed control, although we find that Poa annua and Polygonum aviculare tend to be tolerant. It would be interesting to know whether Dr. Pfeiffer and his colleagues have carried out any work with the horticultural Brassicas.

Dr. R.K. Pfeiffer Not yet, but we plan to investigate this next year, in co-operation with other people.

Mr. S.G. Jary Trials have been carried out in Kent with G34360 and simetryne on 7 varieties of broccoli and 3 of cauliflower. Both compounds were regarded as safe, though there was a very slight phytotoxic effect on some varieties. This damage was, however, of no practical significance.

Mr. A.L. Abel May I first comment on the additional value conferences have in bringing forth from one's colleagues results they have not reported! Regarding other crops so far tested for their resistance to G34360, turnips and swedes appear to be severely damaged at the doses recommended for kale.

Professor G.E. Blackman If this compound is coming on to the market, the fact that it is effective at 4 oz/ac seems to me to put a lot of temptation in the way of commercial colleagues in deciding on what price it should be.

## Research Report

### FIELD TRIALS WITH N-PROPYL-ETHYL-n-BUTYLTHIOL CARBAMATE FOR THE CONTROL OF SEEDLING WEEDS IN SUGAR BEET AND MANGOLDS

B.H. Bagnall, J.J.B. Caldicott and D.J. Minter

The Murphy Chemical Co. Ltd., Wheathampstead, St. Albans.

Summary: Applications of n-propyl-ethyl-n-butylthiolcarbamate\* were made just prior to drilling or shortly after drilling with incorporation by various implements in the top one or two inches of soil. The material was used as a granule as well as in spray form on a range of soil types as both band application and overall applications. The material proved to be sufficiently safe for use on sugar beet and mangolds at 4 lb a i/ac. Weed control varied considerably and is believed to be dependent on the degree of incorporation of the herbicide into the soil. Certain weed species appear more susceptible than others. Granule or spray formulations seemed to be equal in activity. Soil type, soil moisture and rainfall after application do not appear to affect the results greatly. Further work is necessary to improve the range of weed control by the possible admixture of this material with another herbicide.

#### INTRODUCTION

N-propyl-ethyl-n-butylthiolcarbamate, a selective herbicide related to EPTC, has been developed by the Stauffer Chemical Co. for the control of grasses and certain broad-leaf weeds in the U.S.A. The safety of this new thiolcarbamate to sugar beet has been shown both in private communications from the Stauffer Chemical Co. and by report from Burtch (1961). This paper presents the results of field tests on sugar beet and mangolds in 1962, using the chemical as both a miscible and in granular form in comparison with an endothal + propham mixture. The tests were designed to ascertain the weed control spectrum of the new material.

#### METHODS AND MATERIALS

N-propyl-ethyl-n-butylthiolcarbamate has the following structural formula:-

\* as "Tillam" (Stauffer Chemical Co.)

∧ as 'Murbetex' (Murphy Chemical Co. Ltd.)

The pure material is a clear liquid. Its water solubility is 92 ppm at 21°C. The boiling point at 20 mm Hg is 142.5°C. The compound has an acute oral LD50 to rate of 1120 mg/kg (Stauffer 1961). The compound was used in the form of existing formulations supplied by the Stauffer Chemical Co, which were an emulsifiable concentrate containing 72 per cent wt/vol active ingredient and a granular formulation containing 10 per cent wt/wt active ingredient. Since n-propyl-ethyl-n-butylthiolcarbamate has no accepted common name or abbreviation at present, use will be made of its early reference number 'R 2061' for convenience in tables and discussion of results.

Endothal/propham mixture was either the commercial formulation as now available or a special granular formulation containing 4 per cent wt/wt endothal a.e. and 3 per cent wt/wt propham. In each case the endothal/propham mixture was used at doses appropriate to the soil type (Caldicott 1962 and Hunnam and Hey, 1962). All rates of endothal are as lb acid equivalent, propham and 'R 2061' as active ingredient. All are quoted on the basis of overall treatment.

Four series of trials are included in the results section. Layout and technique varied somewhat for each series and therefore it is necessary to describe them in some detail. One factor common to all was that 'R 2061' was used at 4 lb/per ac of area treated. This dose was used since it had been shown to be safe in earlier tests in U.S.A., whereas the 6 lb/ac rate can cause adverse effects to sugar beet, and rates lower than 4 lb/ac have not been sufficient to control weeds.

#### Replicated Spray Trials

These trials at ten sites were experiments involving many chemicals. There were 4 randomised blocks containing plots of 84 sq yd. (12 rows x 12 yd). The treatments were applied in 21 gall water per acre treated, as a 7 in. band over the seed row by a small sprayer described by Bagnall and Minter (1962). 'R 2061' was incorporated into the surface of the soil with a miniature harrow immediately after application. Since spraying was after seeding, it was necessary to use the miniature harrow with care to avoid damage to the beet seed. Incorporation was, therefore, only to a depth of about one inch in these trials. Counts of weeds and beet were made just before singling, when the beet had 2 to 4 leaves. Assessments were made at 5 points within each plot (20 per treatment) using a 50 x 2 in. quadrat, the count being taken along the row. Crop emergence figures were, therefore on a 50 in. length of row and the total of each weed species was recorded for each 100 sq. in. Population counts and vigour assessments were carried out after thinning had taken place.

#### Replicated Granule Trials

These trials, carried out at 3 sites, comprised 4 blocks, containing individual plots of 120 sq yd (16 row x 12 yd). A seven inch band of granules was applied over the seed row by a Noble granular applicator mounted on a wheelbarrow frame and adapted to treat two rows at a time. The granules were incorporated into the soil above the seed with a miniature harrow drawn along the row after the machine. Assessments were the same as for the spray trials.

#### Non-replicated Trials

These trials at 3 centres, were simplified to allow greater incorporation of the 'R 2061' in the top 2 in. of seed bed by applying the material at the time of

seed bed preparation. The spray was applied by a hand-operated Knapsack sprayer and granules were applied by hand using a large tin with a "pepper-pot" lid. The soil was then harrowed several times in two directions to obtain incorporation to a depth of about 2 in. The sugar beet was drilled within a few days. Plot size varied from 75 to 240 sq yd.

#### Replicated Trials on Mangolds

Two trials conducted on this crop were slightly different in design. At the first site the trial was a 4 x 4 latin square, in which 3 materials in granule form were compared with an untreated control. The third material was a compound related to 'R 2061' but the results were not of interest. The plots were each 60 sq yd. At the second site the two thiolcarbamates were compared within a 3 block design, but only the results for 'R 2061' are shown. The granules in each case were applied by hand, using the "pepper-pot" and incorporation was achieved by harrowing the land several times in two directions after application.

#### Further Incorporation Trials

It was considered necessary to improve the method of incorporation of the herbicide into the seed bed and a machine was constructed to provide means of incorporating the herbicide in a seven inch band just before drilling. The machine had to be readily transportable from site to site and, therefore, it was necessary to keep it as light as possible. Considering the length of the machine described by Fryer et al. (1960) a shorter machine was designed for these tests which comprised a unit of four small mid-mounted rotary incorporators with a spray nozzle mounted just in front of each rotavator so as to apply a seven inch band of spray on to the soil. This was incorporated to a depth of 2 in. A normal power-operated precision drill was mounted behind the tractor. A drill unit was in line with each small rotavator. A pulley was fitted to the tractor P.T.O. to allow a drive shaft for both the rotavators and the precision drill.

The spray was supplied from a 30 gal front mounted tank with a  $3\frac{1}{2}$  g.p.m. pump operated from the drive on the precision drill. Controls and pressure gauges were mounted on the tractor within easy access of the driver. The machine was operated at 2 mph. Unfortunately the trials were adversely affected by the method of incorporation which was found to distribute the chemical unevenly.

### RESULTS

Site data, weed and crop seedling populations are shown in Tables I to V. The sites shown in Table I range from light sand to heavy clay loam, with three very black organic soils. Early sown sites suffered badly from the very cold weather in March of this season. Table II shows the results for 3 sites where granules were used. Table III gives more specific weed detail concerning the sites in Tables I and II. Other weeds occurred but only at a limited number of sites. Therefore, they have not been included in this list of results. Tables IV and V give results of pre-drilling applications of 'R 2061'. The weeds occurring in sites referred to in Table IV were chiefly Stellaria media, Chenopodium album, Polygonum convolvulus, and Veronica persica. S. media and V. persica were well controlled, the others to a much lesser extent. Endothal + prophan was used as a comparison treatment since the mixture has a wide spectrum

of weed control which serves as a useful guide to the standard required or the improvement to be looked for in any new material.

## DISCUSSION

### Effect on Sugar Beet and Mangolds

No significant reduction in seedling emergence was found at the rate used under a wide range of soil types and weather conditions. 'R 2061' occasionally causes slight leaf distortion in the early true leaves, but normal growth is resumed later. Generally slow growth in the spring, in which these trials were conducted, exaggerated any adverse symptoms. Therefore, the results obtained would seem to be a satisfactory sign of the safety of 'R 2061' as a herbicide for use on these root crops. Granular and spray forms of the material show equal safety.

### Effects on Weeds

Results appear extremely varied even for given weed species. In general there were no outstanding differences between granule and spray results and therefore the material can be considered in this discussion regardless of formulation.

Reasonable control of some weeds such as S. media, C. bursapastoris and V. persica has been obtained in many circumstances. It is difficult to understand some of the instances of failure to control them because Urtica urens, Poa annua, Geranium pratense and Lamium amplexicaule were well controlled on such occasions. C. album and Polygonum species have been controlled to a rather varied extent. Solanum nigrum where it occurred was not controlled to any noticeable extent.

The value of 'R 2061' for seedling grass control has not been adequately confirmed owing to limited occurrence of such weeds in the trials. The control of C. album, however, was not as good in these trials as that reported from U.S.A. For this reason, as well as the variation in control of other weeds it may be concluded that incorporation was not sufficiently thorough in these early trials where a miniature harrow was used. It is less easy to understand failures where normal farm spike-toothed harrows were used within a short interval of application. The results in Tables IV and V are admittedly more promising than the earlier tests but are rather few in number by comparison. They do appear to offer promise of 'R 2061' providing control of some of the important weeds in root crops.

### Effects of Soil Type and Rainfall

Whereas it has been shown in trials reported by Caldicott (1962) that endothal/propham has an optimum dosage rate dependent on soil type, this is not indicated for 'R 2061'. Indeed even highly organic soils appear to have a less limiting effect on this compound than on many other herbicides. From observations at the time of treatment, variation in soil moisture does not appear to affect the efficiency of 'R 2061'. Rainfall was generally sufficient for the full efficiency of non-incorporated herbicides such as endothal/propham and only at site 18 in Table V was there in fact insufficient rainfall to allow good weed control from an application of endothal/propham in an adjacent trial. The

results at this site show weed control by 'R 2061' to be of a similar order to that obtained at other sites where higher rainfall was recorded in the 1 or 2 weeks after treatment.

From these results it was considered that further trials should be arranged with a more thorough system of incorporation for 'R 2061'. Such trials were carried out at 6 sites, but the rotary incorporators did not give the degree of even distribution of chemical that was required. Tests using polystyrene granules which were spread as a band in front of the rotary devices were later recovered from soil samples taken at different depths. More than twice as many granules were found at 2 in. deep than at 1 in. deep, which served to indicate that the existing blades used on the rotavators were carrying the material down into the soil but not distributing it evenly.

#### CONCLUSION

N-propyl-ethyl-n-butylthiolcarbamate has shown promise for the control of some weeds in sugar beet and mangolds. It seems essential to obtain a more thorough incorporation of the material into the soil than obtained by harrows, springtines or flat-bladed rotary devices. From the results it would seem necessary to mix some other herbicides with this new material to obtain the control of all important weeds which occur in sugar beet and mangolds in Great Britain. If such a mixture can be found, it would have the benefit of giving satisfactory weed control with less dependence on adequate rainfall after treatment, which is a requirement of most existing residual herbicides.

#### Acknowledgements

The authors are indebted to farmers who so willingly co-operated in allowing facilities for trials. Also to Messrs. Dorman Sprayers Ltd., Horstine Farmery Ltd., Stanhay (Ashford) Ltd., and Ernest A. Webb Ltd., for assistance in the supply of machinery. Thanks are also due to Dr. R. Heap of Messrs. Charles Page Ltd., for advice in the early stages of the trials and to the Stauffer Chemical Co. for supply of material.

Mangold population figures showed no reduction in stand due to 'R 2061' or endothal + propham. There was, however, a 25 per cent reduction in vigour of mangolds at site 17 due to 'R 2061'.

## Research Report

### 2,4-DICHLOROPHENYL 4-NITROPHENYL ETHER: A NEW RESIDUAL HERBICIDE

D. Tyson and C.H.P. Wood.

Pan Britannica Industries Limited, Waltham Cross, Herts.

Summary: 2-4-dichlorophenyl 4-nitrophenyl ether ('FW.925') has been found to control successfully a range of common weeds occurring as competitors in a number of important horticultural crops when applied prior to weed and crop emergence. This new residual herbicide possesses three important and unusual properties: a) It is chemically distinct from the residual herbicide at present available. b) Its herbicidal activity is not influenced by the degree of soil moisture at application time. c) Its herbicidal activity is not materially influenced by the type of soil.

In pre-emergence applications garden beet tolerated 2.5 lb/ac 'FW.925' on most soil types although sugar beet was damaged by this dose; Brassicæ and peas were not affected by 5 lb/ac 'FW.925' but lettuce was occasionally damaged by 2.5 lb/ac 'FW.925'. Weeds controlled at doses of 2.5-10 lb/ac of 'FW.925' per acre included Urtica urens, Poa annua, Veronica spp., Chenopodium album, Polygonum persicaria, P. aviculare, Lamium purpureum, and L. amplexicaule. The effect upon Capsella bursa-pastoris and Senecio vulgaris increased as the dose was increased. Stellaria media was resistant to 10 lb/ac 'FW.925'. The effect of 'FW.925' on susceptible weeds persisted for 6 weeks. The weed spectrum controlled was improved by mixing 'FW.925' with minimum amounts of chlorpropham, CDEC, or N'-4-(4-chlorophenoxy) phenyl-NN-dimethyl urea ('1983') although at the expense of the selectivity on some soil types. Post weed and crop emergence applications of 'FW.925' at 2.5 lb/ac controlled Urtica urens, Calystegia sepium and Convolvulus arvensis, although regrowth occurs afterwards from roots of the latter two. Peas and carrots, gooseberry and rose bushes tolerated 2.5 lb/ac 'FW.925' and Brassicæ were not affected by 5 lb/ac 'FW.925' as post-emergence applications.

## INTRODUCTION

2-4-dichlorophenyl 4-nitrophenyl ether ('FW.925') has shown promise as a selective herbicide in trial work in the U.S.A. 'FW.925' is extremely insoluble in water and has an acute oral toxicity of the technical grade to rats of approximately 2630 mg/kg body weight.

It was apparent from the American screening work that the herbicidal effect of 'FW.925' is exerted on the young shoot as it emerges above the soil. Primary work in Great Britain agreed with the American findings that optimum weed control was obtained by leaving 'FW.925' undisturbed on the soil surface-incorporation into the soil invariably resulted in very poor herbicidal action. The weed spectrum controlled was comprehensive, although Senecio vulgaris and Capsella bursa-pastoris appeared moderately resistant, and Stellaria media resistant to normal application rates.

The 1961/1962 field evaluation work was planned to investigate the herbici-

dal effect of 'FW.925' when used on different soil types growing a variety of crops for which residual herbicides were either not available or not recommended.

Collateral work was also undertaken to determine the value of mixtures of 'FW.925' with chlorpropham because of its known ability to control Stellaria media at low application rates, with CDEC as a result of observations that it might enhance the herbicidal action of 'FW.925', and with '1983' which had given indications of good control of Capsella bursa-pastoris, Senecio vulgaris and Stellaria media.

The experimental results given below are typical of those achieved in 1961/1962.

#### METHODS AND MATERIALS

- 'FW.925' - 2-4-dichlorophenyl 4-nitrophenyl ether, formulated as an emulsifiable concentrate,
- CDEC - 2-chloroallyl-NN-diethyl-dithiocarbamate, formulated as an emulsifiable liquid,
- '1983' - N'-4-(4-chlorophenoxy)phenyl-NN-dimethyl urea, formulated as a wettable powder,
- chlorpropham - Isopropyl-N-(3-chlorophenyl)carbamate, formulated as an emulsifiable liquid.

The herbicides were applied through an Oxford Precision Sprayer at doses ranging from 40 to 300 gal water/ac, usually at 100-150 gal/ac using size 0 nozzles. The plot layout was generally in randomized blocks with fourfold replication. Weed control data was based upon six or more quadrat counts from each plot. The grading of the crop seedlings was based on visual assessment by at least two observers using the control plots as the standard for comparison. The grades used were:-

- 0 - no noticeable effect upon germination or subsequent appearance. The crop can be expected to mature without any loss in yield.
- 1 - a noticeable effect but no sign of severe damage. In some cases the affected crop matures normally with no loss in yield.
- 2 - severe damage or completely killed. Invariably the affected crop will either not mature or show depressed yields.

#### RESULTS

##### Application prior to crop and weed emergence

The results are presented in tables I to XI

TABLE I - RED GLOBE BEET

Peat fen (50.3 per cent organic matter, pH 6.2). Soil prepared May 15; crop sown May 18; sprayed May 18 after sowing - soil surface very dry with some moisture underneath; 0.56 in. rain within 24 hr., then dry for 6 days.

\* applied through '3' nozzles

#### Application after weed emergence

2-6 lb/ac of 'FW.925' controlled Urtica urens, and checked Veronica spp. but did not control Chenopodium album, Polygonum persicaria, Stellaria media, Capsella bursa-pastoris, Senecio vulgaris. Aerial growth of Calystegia sepium and Convolvulus arvensis was killed by 2.5 lb/ac but regrowth occurred later from the roots.

#### Application after crop emergence

Peas, carrots, gooseberry and rose bushes were not affected by 2.5 lb/ac of 'FW.925', while Brassica crops were unaffected at 5 lb/ac.

#### DISCUSSION

##### The herbicidal effect of 'FW.925'

The trials where 'FW.925' was applied prior to weed emergence have shown that it can give acceptable control of certain weed species such as Urtica urens, Polygonum persicaria, Veronica spp., and Poa annua, which are a problem in market garden crops under a wide variety of soil moisture conditions. Chenopodium album was adequately controlled in the trials, especially where climatic or cultural conditions encouraged the rapid emergence of the weed shortly after spraying; as occurred in III, IV, V and III. In Tables VII, VIII and IX where adverse conditions gave a delayed or prolonged emergence of C. album this weed was significantly checked in growth for at least 42 days, thus demonstrating the persistence of the herbicide.

'FW.925' did not control Stellaria media at the doses used; also Capsella bursa-pastoris and Senecio vulgaris were not well controlled - although the con-
